

# CS-417 INTRODUCTION TO ROBOTICS AND INTELLIGENT SYSTEMS

**Particle Filters** 

#### **Bayesian Filter**

- Estimate state **x** from data **Z** 
  - What is the probability of the robot being at x?
- x could be robot location, map information, locations of targets, etc...
- Z could be sensor readings such as range, actions, odometry from encoders, etc...)
- This is a general formalism that does not depend on the particular probability representation
- Bayes filter **recursively** computes the posterior distribution:  $Bel(x_T) = P(x_T \mid Z_T)$

#### **Iterating the Bayesian Filter**

Propagate the motion model:

$$Bel_{-}(x_{t}) = \int P(x_{t} \mid a_{t-1}, x_{t-1}) Bel(x_{t-1}) dx_{t-1}$$

Compute the current state estimate before taking a sensor reading by integrating over all possible previous state estimates and applying the motion model

Update the sensor model:

$$Bel(x_t) = \eta P(o_t \mid x_t) Bel_{-}(x_t)$$

Compute the current state estimate by taking a sensor reading and multiplying by the current estimate based on the most recent motion history

# Mobile Robot Localization (Where Am I?)

- A mobile robot moves while collecting sensor measurements from the environment.
- Two steps, action and sensing: (χ,γ,θ)
  - Prediction/Propagation: what is the robots pose x after action A?
  - Update: Given measurement z, correct the pose x'
- What is the probability density function (pdf) that describes the uncertainty  $\mathbf{P}$  of the poses  $\mathbf{x}$  and  $\mathbf{x}'$ ?

#### **State Estimation**

Propagation

$$P(x_{t+1}^- \mid x_t, \alpha)$$

Update

$$P(x_{t+1}^+ \mid x_{t+1}^-, z_{t+1})$$

#### **Traditional Approach Kalman Filter**

- Optimal for linear systems with Gaussian noise
- Extended Kalman filter:
  - Linearization
  - Gaussian noise models
- Fast!

# Monte-Carlo State Estimation (Particle Filtering)

- Employing a Bayesian Monte-Carlo simulation technique for pose estimation.
- A particle filter uses N samples as a discrete representation of the probability distribution function (pdf) of the variable of interest:

$$S = [\vec{\mathbf{x}}_i, w_i : i = 1 \cdots N]$$

where  $x_i$  is a copy of the variable of interest and  $w_i$  is a weight signifying the quality of that sample.

In our case, each particle can be regarded as an alternative hypothesis for the robot pose.

#### Particle Filter (cont.)

The particle filter operates in two stages:

• Prediction: After a motion  $(\alpha)$  the set of particles S is modified according to the action model

$$S' = f(S, \alpha, \nu)$$

where (v) is the added noise.

The resulting *pdf* is the <u>prior</u> estimate before collecting any additional sensory information.

#### Particle Filter (cont.)

• **Update:** When a sensor measurement (z) becomes available, the <u>weights</u> of the particles are updated based on the likelihood of (z) given the particle  $x_i$ 

$$w_i' = P(z \mid \vec{\mathbf{x}}_i) w_i$$

The <u>updated particles</u> represent the posterior distribution of the moving robot.

#### **Remarks:**

- **In theory**, for an infinite number of particles, this method models the true *pdf*.
- **In practice**, there are always a finite number of particles.

#### Resampling

For finite particle populations, we must focus population mass where the *PDF* is substantive.

- Failure to do this correctly can lead to divergence.
- Resampling needlessly also has disadvantages.

One way is to estimate the need for resampling based on the variance of the particle weight distribution, in particular the coefficient of variance:

$$cv_t^2 = \frac{\text{var}(w_t(i))}{E^2(w_t(i))} = \frac{1}{M} \sum_{i=1}^{M} (Mw_t(i) - 1)^2$$

#### **Prediction: Odometry Error Modeling**

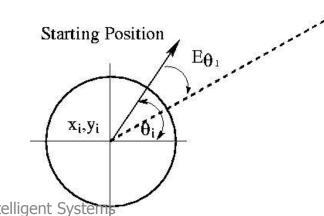

- Piecewise linear motion: a simple example.
- **Rotation**: Corrupted by Gaussian Noise.
- **Translation**: Simulated by multiple steps. Each step models

translational and rotational error.

#### Single step:

Small *rotational* error (drift) before and after the translation.

Translational error proportional to the distance traveled.

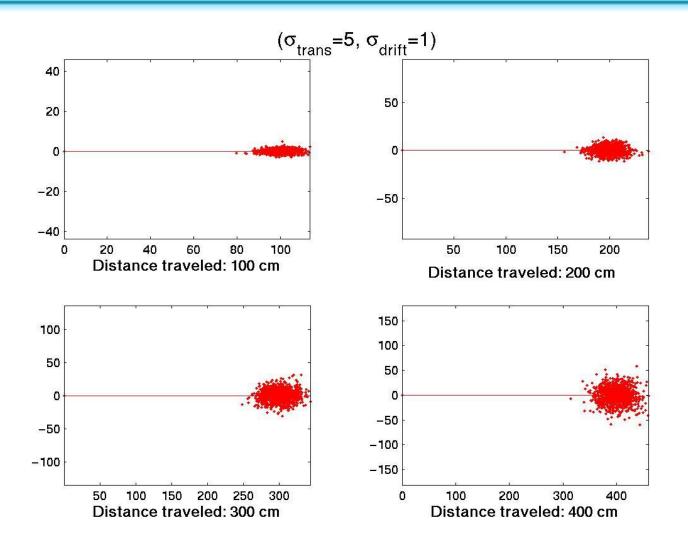

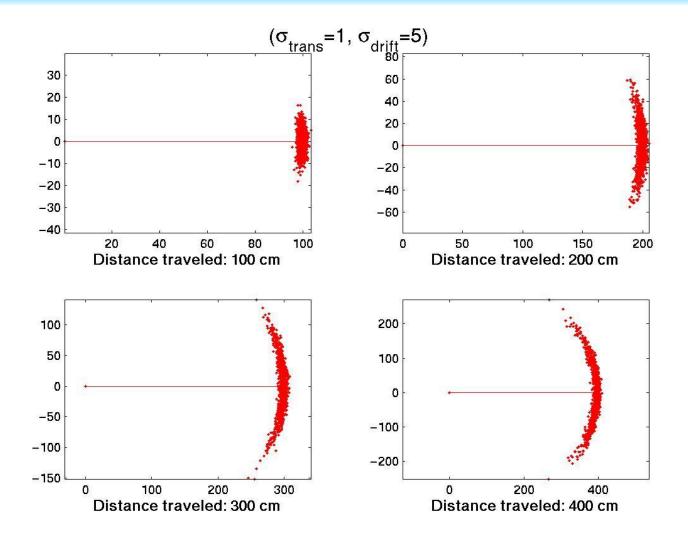

All errors drawn from a Normal Distribution.

 $x_{i+1}y_{i+1}$ 

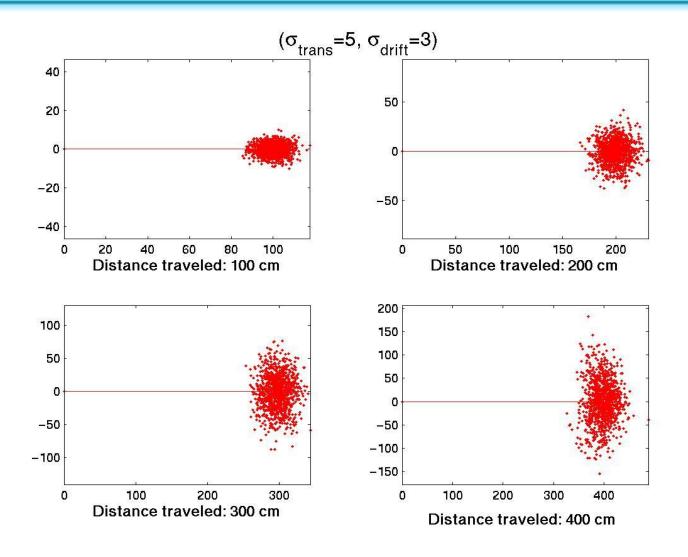

Finishing Position

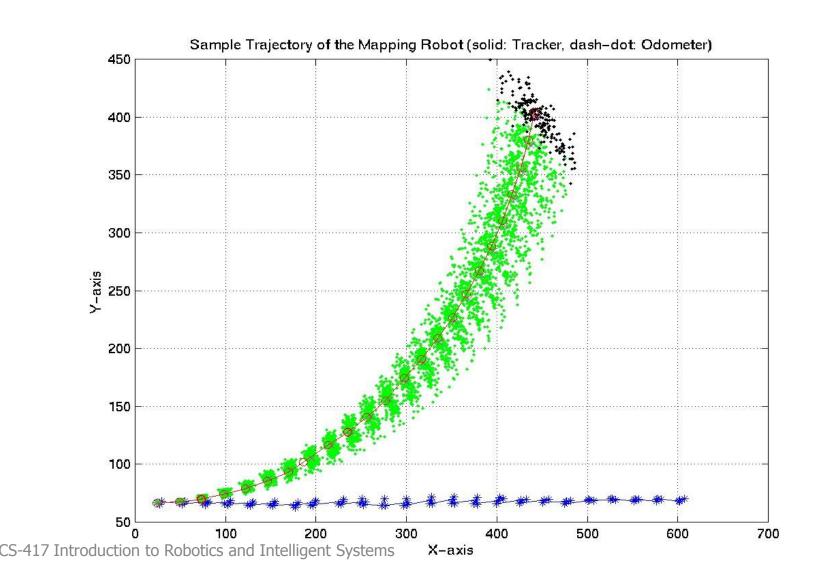

#### **Prediction-Only Particle Distribution**

#### Propagation of a discrete time system

 $(\delta t=1 sec)$ 

$$x_{i}^{t+1} = x_{i}^{t} + (v_{t} + w_{v_{t}}) \delta t \cos \phi_{i}^{t}$$

$$y_{i}^{t+1} = y_{i}^{t} + (v_{t} + w_{v_{t}}) \delta t \sin \phi_{i}^{t}$$

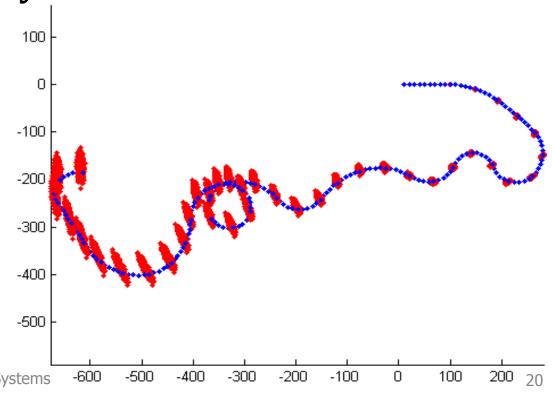

$$\phi_{i}^{t+1} = \phi_{i}^{t} + (\omega_{t} + w_{\omega_{t}}) \delta t$$

Where  $W_{v_t}$  s the additive noise for the linear velocity, and

 $W_{\omega_i}$  is the additive noise for the angular velocity

#### **Continuous motion example**

- Dt=1sec
- Plotting 1 sample/sec all the particles every 5 sec
- Constant linear velocity
- Angular velocity changes randomly every 10 sec

## **Continuous motion example**

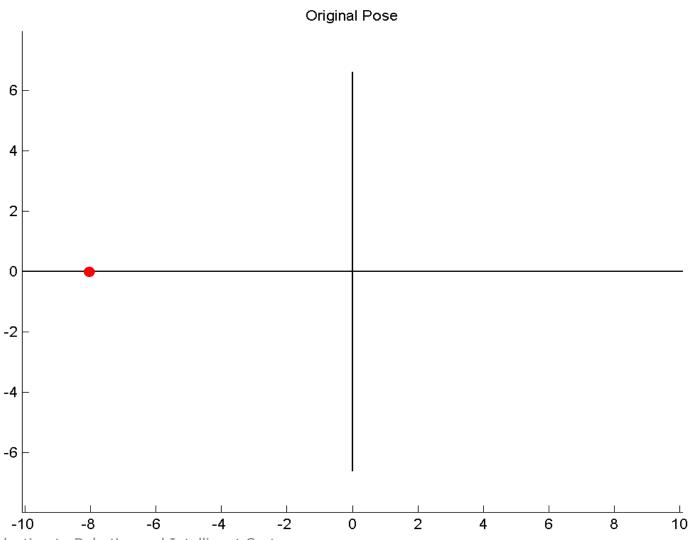

#### **Prediction Examples Using a PF**

#### Piecewise linear motion

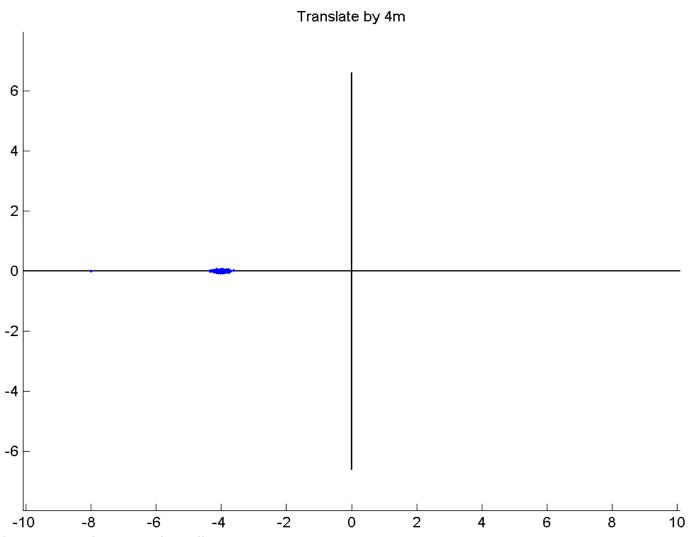

(Translation and Rotation)

- Command success 70%
- Start at [-8,0,0]
- Translate by 4m
- Rotate by 30°
- Translate by 6m

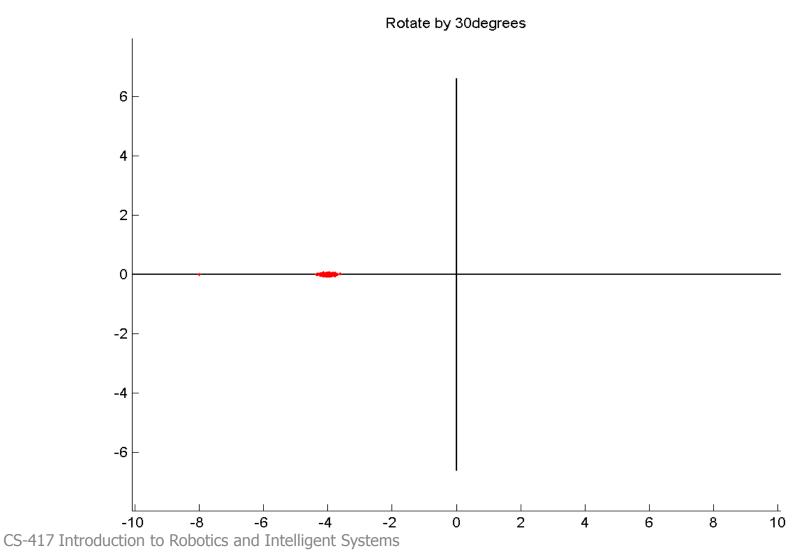

# Start [-8,0,0°]

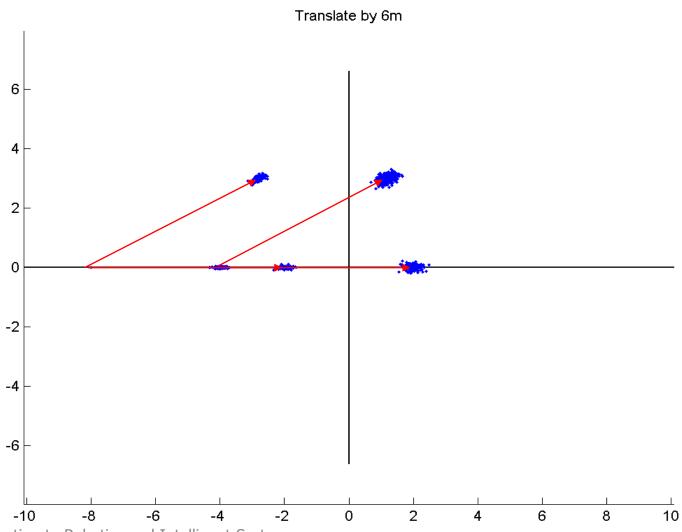

## **Translate by 4m**

## Rotate by 30°

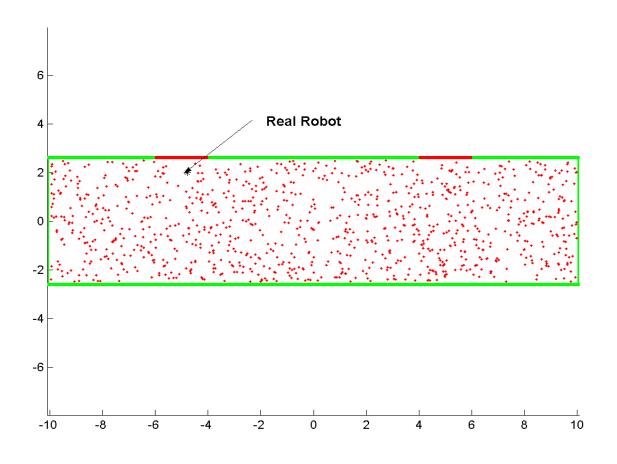

## **Translate by 6m**

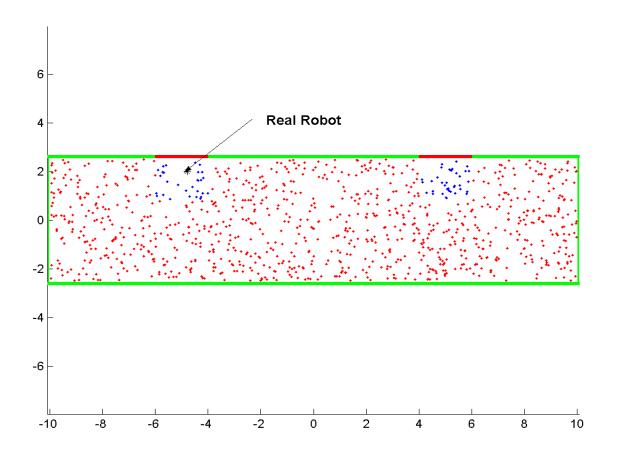

## **Update Examples Using a PF**

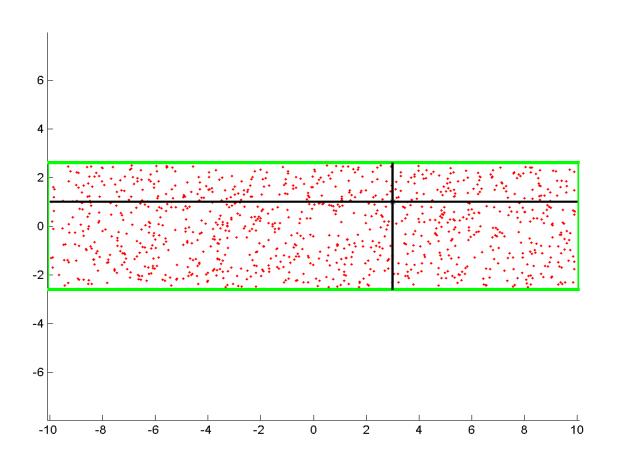

# Environment with two red doors (uniform distribution)

# Environment with two red doors (Sensing the red door)

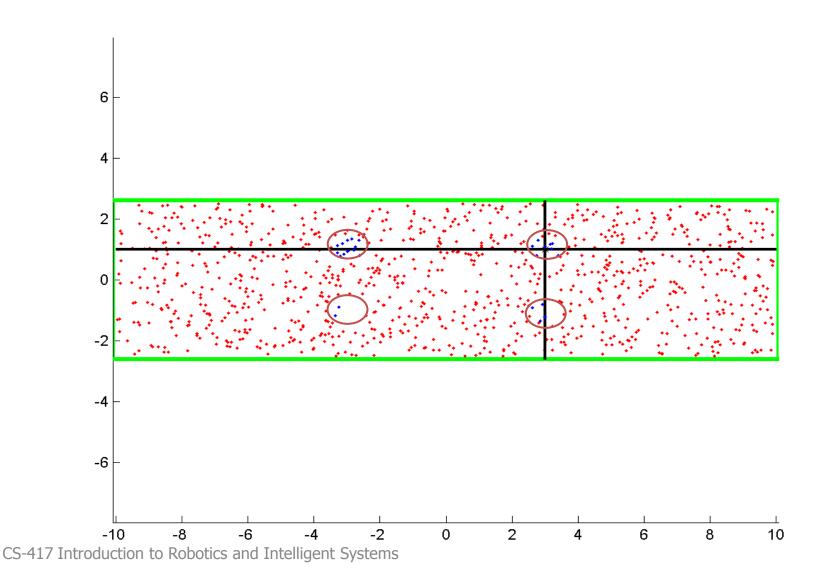

# **Sensing four walls**

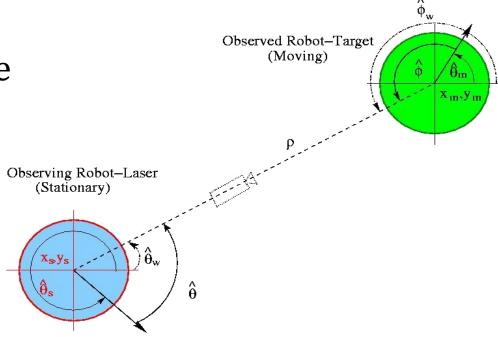

## Four possible areas

#### **Cooperative Localization**

 Pose of the moving robot is estimated relative to the pose of the stationary robot.

Stationary Robot observes the Moving Robot.

#### **Robot Tracker Returns:**

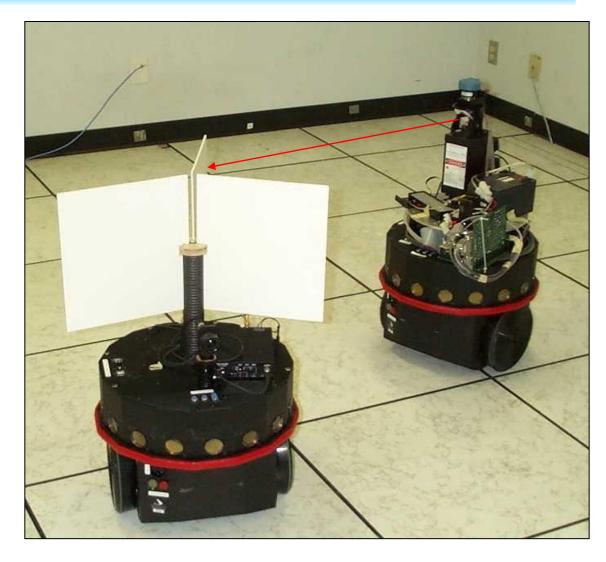

$$\mathbf{x}_{m_{est}}(k+1) = \begin{pmatrix} x_{m_{est}} \\ y_{m_{est}} \\ \theta_{m_{est}} \end{pmatrix} = \begin{pmatrix} x_{s} + \rho \cos(\theta + \theta_{s}) \\ y_{s} + \rho \sin(\theta + \theta_{s}) \\ \pi - (\phi - (\theta + \theta_{s})) \end{pmatrix}$$

#### **Laser-Based Robot Tracker**

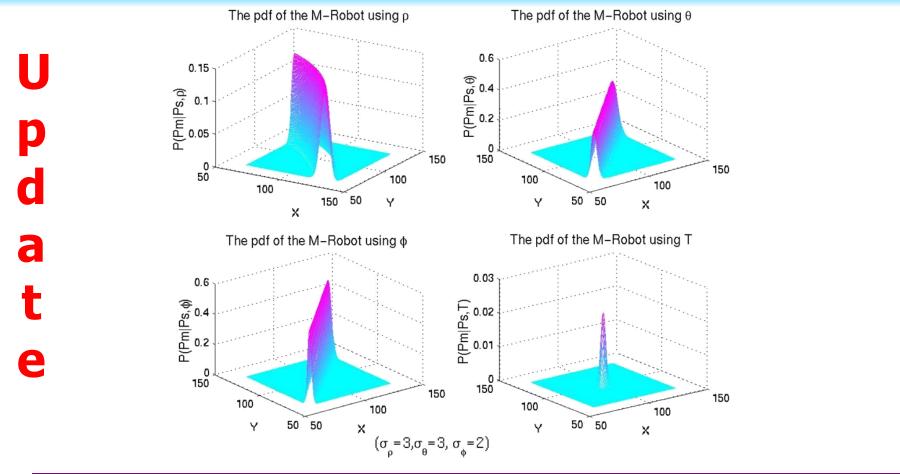

**Robot Tracker Returns:** 

<ρ,θ,φ>

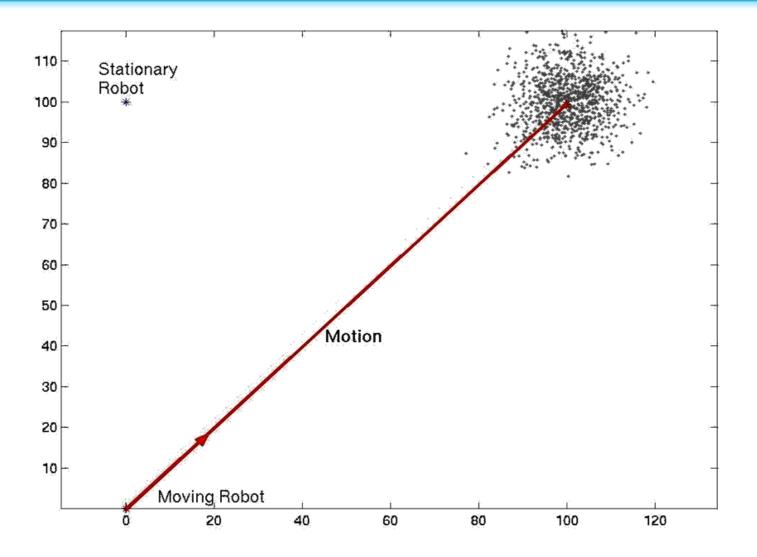

### **Tracker Weighting Function**

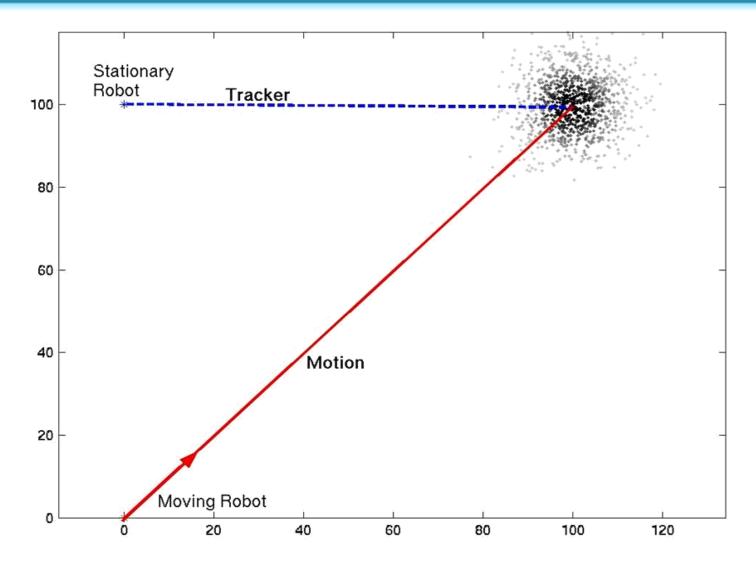

$$W = \frac{1}{\sqrt{2\pi\sigma_{\rho}^{2}}} e^{\frac{-(\rho - \rho_{i})^{2}}{\sigma_{\rho}^{2}}} \frac{1}{\sqrt{2\pi\sigma_{\theta}^{2}}} e^{\frac{-(\theta - \theta_{i})^{2}}{\sigma_{\theta}^{2}}} \frac{1}{\sqrt{2\pi\sigma_{\phi}^{2}}} e^{\frac{-(\phi - \phi_{i})^{2}}{\sigma_{\phi}^{2}}}$$

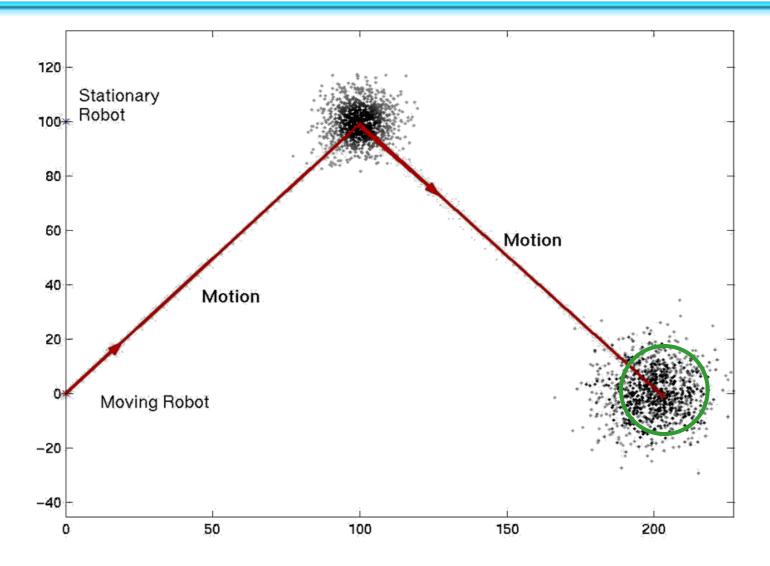

## **Example: Prediction**

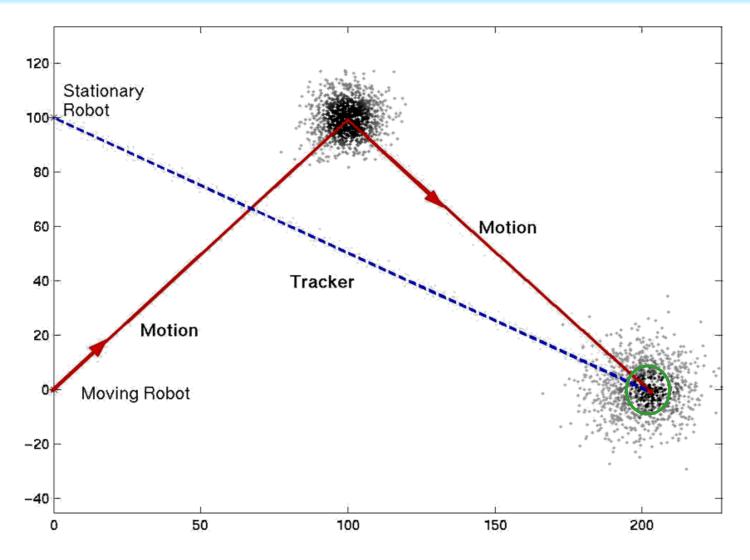

#### **Example: Update**

# **Example: Prediction**

#### **Example: Update**

#### **Variations on PF**

- Add some particles uniformly
- Add some particles where the sensor indicates
- Add some jitter to the particles after propagation
- Combine EKFs to track landmarks

#### **Keep in Mind:**

• The number of particles increases with the dimension of the state space

#### **Complexity results for SLAM**

- n=number of map features
- Problem: naïve methods have high complexity
  - EKF models O(n^2) covariance matrix
  - PF requires prohibitively many particles to characterize complex, interdependent distribution
- Solution: exploit conditional independencies
  - Feature estimates are independent given robot's path

#### **Rao-Blackwellization**

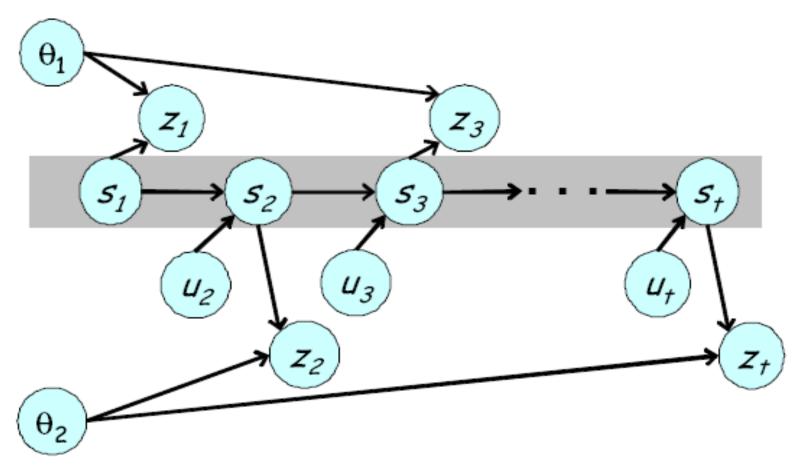

Figure from [Montemerlo et al – Fast SLAM]

#### **RBPF Implementation for SLAM**

- 2 steps:
  - Particle filter to estimate robot's pose
  - Set of low-dimensional, independent EKF's (one per feature per particle)
- E.g. FastSLAM which includes several computational speedups to achieve O(M logN) complexity (with M number of particles)
